ABSTRACT

Climatic parameters in time and space scales of change are for many reasons of Changes and how they should be based on observations using a statistical method to be determined. Analysis of the most widely used statistical methods that assess potential climate change on hydrological time series, such series of precipitation, temperature and flow rate used. This study of 11 synoptic, rain gage and climatology stations with 30 years during the years 1979 to 2009 period is Charmahal o Bakhtiari province. Mann-Kendall non-parametric and Sen estimate tests were used for the purpose of the study. The results showed that 11 stations were the only station in sepid dasht 95 and 99 percent had significant levels decline and changes in the slope is negative and other gage stations does not have significant trends. The results of this study can be in the long-term planning for water resources management, irrigation scheduling and prediction of future droughts in the province can be used.

Keywords: Precipitation Changes, Mann-Kendall Test, Sen Estimate Test, Charmahal o Bakhtiari

INTRODUCTION

The phenomenon of climate change has been occurred as result of increasing greenhouse gases concentration and human activities in atmosphere causes to change temporal and spatial of water resources in watersheds in twenty one century (Kanzvis et al., 2007). The capacity of vapor sustenance in atmosphere increases with climate warming. So, the water returns to hydrological cycle rapidly which potentially increase the frequency of hydrological events
(Hangtigon, 2006). The rate of stored water in water resources changes in different times of hydrological cycle because of the increasing precipitation variations and increasing temperature (Hejen and Van, 2010). Indeed, the existence of trend in temporal series of meteorology is due to the gradual natural change and climate change or the effects of human activities (Bayersen et al., 2005; Jiang et al., 2007; Vesmaket and Bern, 1997). The identification of the variations in long duration series of hydrological data is a most important problem which persuades researchers to provide basal maps of water resources and prohibit from flood risk in future (Zdenek and Milada, 2008). The plans usually form based on stationary hypothesis in hydrological series which the previous data of precipitation are used to predict future (Kundzewicz and Robson, 2008). The analysis of the temporal hydrological trend is important to help researches and management of water resources to understand the climate change and its effect on water resources (Becker et al., 2006; Burn and Hag Elnur, 2002; Kahya and kalayci, 2004; Xu et al.,2007). The trend analysis is used to evaluate the effect of potential of climate change and its variability on temporal hydrological series in different region of the world (Khaled and Hamed, 2008). The determining of trends in hydrology, climate, water quality and other natural temporal series has been more attended in three recent decades. In recent years the extensive researches have been done about climate change and its variability which more attention has focused on determination of trend. For example Carbajal et al. (1993) in Aconcagua river basin investigated the temperature and precipitation using Mann-Kendall test. This study didn’t show the significant trend in precipitation whereas there was significant increasing trend in temperature. Kampata et al. (2008) in Zambezi River Basin in Zambia investigated the long term precipitation data collected from 5 rain gauge stations to determine the temporal series have same regime or significant trend. The Mann-Kendall test was used to determine the trend. each 5 stations show the decreasing trend but these trends were not significant. An investigation was conducted by zangxu et al. (2010) in Tarim river basin in North West of china in a 50-year statistical period. Results showed that the mean annual temperature and annual precipitation had increasing trend whereas the annual discharge had an increasing and decreasing trend. The upward of mountainous region had increasing trend and downward decreasing. Fisher et al. (2010) conducted a study in watershed of Zhujing river in south of china in a statistical period 1961-2001. Results showed that a positive significant trend (significant at probability level of 90%) in annual temperature of warm days and without rainfall within the watershed especially in western and coastal parts, whereas there is negative trend in cold days and moist periods. Although there wasn’t significant trend in maximum precipitation and mean annual but, lengthens of dry period and shorten of moist period can be observed by the reduction of rainy days. In recent years several researches about trend variations of hydrological and meteorological parameters was carried out in Iran. Sohrabi et al. (2009) in a study investigated the annual precipitation of 23 stations in Hamedan province from 1982-2006 using Mann-Kendall test. Results showed that there was significant increasing trend (at probability level of 5%) in Aghajanblaghy, Toiserkan and Ghahavand and for other it was stable. In some stations there was significant trend with increasing and decreasing trend. Hejam et al. (2008) investigated the variations of seasonal and annual rainfall in several selected stations in central basin of Iran using non-parametric methods. Results indicated that the Mann-Kendall method and Sen Estimator method are same in analysis of the trend of seasonal and annual rainfall. The performance of Sen Estimator method is better than Mann-Kendall method in observation analysis which the number of zero data (lack of rainfall) is high. The results of this research shows the significant decreasing trend in both of applied test on some temporal series, but there was no significant increasing trend for both of tests. They concluded that it cannot possible to consider an especial trend for seasonal and annual rainfall in region because of the insufficient number of series with significant trend as compared to
without trend series. The objective of this study was to determine the trend of precipitation variations in Chaharmahal O Bakhtiari province in a 31-year time period (1979-2009) using Sen Estimator method and Mann-Kendall method. Results of this study can be used in scheduling water resources management and drought zoning in future.

MATERIALS AND METHODS

Description of the study area

Chaharmahal O Bakhtiari province with an area 16532 km² is located between the 31° 9´ to 32° 48´ northern latitude and 49° 28´ to 51° 25´ eastern longitude. This province is located in central parts of Zagros mountain between the within mountains and Esfahan province. It is limited to Esfahan province in north and east direction, Khozestan province from west and Kokuloyeh O Boier ahmad from south and Lorestan from west.

Figure 1. The geographical position of Chaharmahal O Bakhtiari province in Iran

Precipitation including rain and snow are two main resources of Karoon and Zayandehrood rivers and watersheds of these two rivers with an area of 13800 and 2720 km². The elevations of Zagroos form the watersheds of Dez, Karkheh, Karoon and Zayandehrood rivers. These areas provide 45 to 50 percent of water resources according to volume of precipitation, low evaporation and suitable condition of geology.

Rainfall data

The annual rainfall of 11 synoptic station, rain gauge and climatology with 30-year statistical period from 1979-2009 was used in this study. The homogenous condition of data was investigated using linear regression method and duplicate mass method. The stations were used in this study had missed data lower than 5% in total periods. In cases which there were
significant and acceptable relationship among stations with defect data the missed data was estimated using linear regression.

**Figure 2.** Spatial distribution of stations

**Analysis Method**

Hydrological process is usually recognized as stationary process. There is evidence which showed many of temporal hydrological series had long term trend and variability. This may due to the effects of human activities and natural system of earth climate.

**Mann-Kendall test**

Many studies show that the Mann-Kendall test is as effective technique in evaluating even variation in temporal series in time (Brooks and Carrthers, 1982). Mann-Kendall test is based on the difference \((x_i-x_k)\) in years having rainfall in temporal periods \((X_1,...,X_N)\). \(S\) is calculated based on total signs (it is always between -1, 0 and 1). In cases which \(N>10\) the standard \(Z\) is calculated as following:

\[
S = \sum_{k=1}^{n-1} \sum_{j=k+1}^{n} \text{sgn}(x_j - x_k) \tag{1}
\]

Which:

\[
\text{sgn}(x_j - x_k) = \begin{cases} 
+1 & \text{if } x_j > x_k \\
0 & \text{if } x_j = x_k \\
-1 & \text{if } x_j < x_k 
\end{cases} \tag{2}
\]
n is sample size. The $S$ has approximately normal distribution when $n \geq 10$ and the mean and variance is as following:

$$E(S) = 0$$ \hspace{1cm} [3]$$

$$V(S) = \frac{n(n-1)(2n+5) - \sum_{i=1}^{n} t_i(i - 1)(2i + 5)}{18}$$ \hspace{1cm} [4]$$

Which $t_i$ is the number of the snarl with a size of $i$. Standard $Z$ for one limit test is as equation [5]:

$$Z = \begin{cases} 
\frac{S - 1}{\sqrt{Var(S)}} & S > 0 \\
0 & S = 0 \\
\frac{S + 1}{\sqrt{Var(S)}} & S < 0 
\end{cases}$$ \hspace{1cm} [5]$$

Which positive value of $Z$ shows the increasing trend and negative value shows decreasing trend. If $|Z| > 1.960$ and $|Z| > 2.576$ the zero hypothesis of lacking trend is rejected.

**Sen Estimator method**

There is quantitative trend to estimate true gradient (variation per year). Non-parametric of Sen is used (Sen, 1998). This test is used in cases which the hypothesis for trend is as linear. This means that the $F(t)$ in equation [6] is as:

$$F(t) = Q_t + B$$ \hspace{1cm} [6]$$

In this equation the $Q$ is a gradient and B is constant value. At first the gradient of all pair values must be calculated to estimate gradient in equation [7]:

$$Q_{ij} = \frac{X_j - X_k}{j - k}, \quad j > k$$ \hspace{1cm} [7]$$

If $n$ to $X_i$ values be in temporal series the number of estimated gradient will calculate by $N - \frac{n^2 - 1}{2}$ (Khaliq et al., 2009). the estimated gradient of sen test is the median of the N numbers of $Q_i$. A two side confidence distance in limit of gradient estimation can be calculated using this non-parametric technique based on normal distribution. In this study the confidence distance was calculated at both level of $X=0.01$ and $X=0.05$. At first the $C_{\alpha}$ is calculated as following:

$$C_{\alpha} = Z_{1-\alpha/2} \sum Var(S)$$ \hspace{1cm} [8]$$
Which $Z_{1-\alpha/2}$ was obtained from normal standard distribution. Then $M_1 = (N - Co)/2$ and $M_2 = (N + Co)/2$ are calculated. The $Q_{\text{min}}$ and $Q_{\text{max}}$ are the lower and higher rate of confidence distance. $M_1$ is largest and $(M_2+1)$ is larger than $N$ estimated gradient arranged $Q_i$. The differences of $x_i-Q_t$ are calculated to estimate $B$ in equation [6]. The median of these values will be an estimation of $B$ for different confidence distance (Sen, 1998). The positive rate of gradient shows the increasing trend and negative rate of gradient shows the decreasing trend (Xu et al., 2008).

RESULTS

The rate of precipitation and the water potential can be measured in each geographical region through measuring annual rainfall. The mean annual precipitation in of Chaharmahal O Bakhtiari province was 528.86 mm. So, according to province area (16532 km²) it can expect to discharge 8743.27 MCM of moisture potential of air. Figure 3 shows the name of selected stations as well as the values of mean annual precipitation and standard deviation of data from 1979 to 2009. According to Figure 3 the mean annual precipitation in Brojen and Kohrang stations were 244.3 and 1422.3 mm, respectively which were the minimum and maximum rate of precipitation in selected stations of Chaharmahal O Bakhtiari province. The analysis result of the trend variation in annual precipitation using Mann-Kendall test in selected stations of Chaharmahal O Bakhtiari province and Sen Estimator method has been illustrated in Figure 4. Results indicates that the Sepid dasht station had decreasing trend at probability level of 95% and 99%, whereas other studied stations had no significant trend at probability level of 95% and 99%.

** Significant trend at probability level of 99%

DISCUSSION AND CONCLUSIONS

According to the Mann-Kendall test more than 81% of stations had no significant trend at probability level 95 and 99% and only Sepid dasht station which has been located in eastern parts of province had significant trend at probability level of 95 and 99%. This result was in agreement with Sen Test and Hejam et al. (2008) about annual precipitation variations in some selected stations in central watersheds of Iran. Each of studied stations had no significant trend. Results of the Kampata et al. (2008) in investigation of the long term data of precipitation in 5 stations of Zambezi River Basin in Zambia showed that the trend was significant in each 5 stations. The precipitation is one of the most effective climate factors in hydrological studies in watersheds, so the temporal and spatial variation and stability and instability in temporal series must be determined using statistical tests to better decision making in management of watersheds. It is better for the researchers to do applicable researches on precipitation and other effective factors in control and utilization of water sources in Iran watersheds to prepare management programs in true direction.
